The Weatherspoon Humidity Modifier System is a new technology to fighting wildfires in drought stricken areas. The system is a network of nebulizers lining the parameter of the landscape, and structures. Each nozzle produces an output of aerosolized, which will increase the moisture in the areas to be protected. . The system is a closed system under 65- 100 psi of pressure sending water up to 60- 100 yards from each nozzle port into the air. My nozzles output are 30 gallons of aerosolized water per hour manually raising the relative humidity and removing the voraciousness out the fire. When the system continues to disburse water the areas will reach rain out and began to deposit moist on the ground reducing the spread of fire. My system can be monitored and operated remotely by through satellite transmission. The water for the system can come from nearby oceans or lakes.
